Type Package

Title Regression Models for Ordinal Data

Version 2015.6-28

Date 2015-06-28

LazyData true

ByteCompile yes

**Depends** R (>= 2.13.0), methods

Imports ucminf, MASS, Matrix

**Suggests** lme4, nnet, xtable, testthat (>= 0.8)

Description Implementation of cumulative link (mixed) models also known as ordered regression models, proportional odds models, proportional hazards models for grouped survival times and ordered logit/probit/... models. Estimation is via maximum likelihood and mixed models are fitted with the Laplace approximation and adaptive Gauss-Hermite quadrature. Multiple random effect terms are allowed and they may be nested, crossed or partially nested/crossed. Restrictions of symmetry and equidistance can be imposed on the thresholds (cut-points/intercepts). Standard model methods are available (summary, anova, drop-methods, step, confint, predict etc.) in addition to profile methods and slice methods for visualizing the likelihood function and checking convergence.

License GPL (>= 2)

# Description

This package facilitates analysis of ordinal (ordered categorical data) via cumulative link models (CLMs) and cumulative link mixed models (CLMMs). Robust and efficient computational methods gives speedy and accurate estimation. A wide range of methods for model fits aids the data analysis.

ordinal-package 3

#### **Details**

Package: ordinal
Type: Package
License: GPL (>= 2)

LazyLoad: yes

This package implements cumulative link models and cumulative link models with normally distributed random effects, denoted cumulative link mixed (effects) models. Cumulative link models are also known as ordered regression models, proportional odds models, proportional hazards models for grouped survival times and ordered logit/probit/... models.

Cumulative link models are fitted with clm and the main features are:

- A range of standard link functions are available.
- In addition to the standard location (additive) effects, scale (multiplicative) effects are also allowed.
- nominal effects are allowed for any subset of the predictors these effects are also known as partial proportional odds effects when using the logit link.
- Restrictions can be imposed on the thresholds/cut-points, e.g., symmetry or equidistance.
- A (modified) Newton-Raphson algorithm provides the maximum likelihood estimates of the parameters. The estimation scheme is robust, fast and accurate.
- Rank-deficient designs are identified and unidentified coefficients exposed in print and summary methods as with glm.
- A suite of standard methods are available including anova, add/drop-methods, step, profile, confint.
- A slice method facilitates illustration of the likelihood function and a convergence method summarizes the accuracy of the model estimation.
- The predict method can predict probabilities, response class-predictions and cumulative probabilities, and it provides standard errors and confidence intervals for the predictions.

Cumulative link mixed models are fitted with clmm and the main features are:

- Any number of random effect terms can be included.
- The syntax for the model formula resembles that of lmer
- Nested random effects, crossed random effects and partially nested/crossed random effects are allowed.
- Estimation is via maximum likelihood using the Laplace approximation or adaptive Gauss-Hermite quadrature (one random effect).
- Vector-valued and correlated random effects such as random slopes (random coefficient models) are fitted with the Laplace approximation.
- Estimation employs sparse matrix methods from the Matrix package.
- During model fitting a Newton-Raphson algorithm updates the conditional modes of the random effects a large number of times. The likelihood function is optimized with a general purpose optimizer.

4 addterm.clm2

In addition to the reference manual several vignettes describe aspects of the package. Two brief tutorials on clm and clmm introduces the use of these functions. The Primer vignette is a 30-page introduction to cumulative link models.

A major update of the package in August 2011 introduced new and improved implementations of clm and clmm. The old implementations are available with clm2 and clmm2. At the time of writing there is functionality in clm2 and clmm2 not yet available in clm and clmm. This includes flexible link functions (log-gamma and Aranda-Ordaz links) and a profile method for random effect variance parameters in CLMMs. The new implementations are expected to take over the old implementations at some point, hence the latter will eventually be deprecated and defunct.

### **Examples**

```
## A simple cumulative link model:
fm1 <- clm(rating ~ contact + temp, data=wine)
summary(fm1)

## A simple cumulative link mixed model:
fmm1 <- clmm(rating ~ contact + temp + (1|judge), data=wine)
summary(fmm1)</pre>
```

addterm.clm2

Try all one-term additions to and deletions from a model

# Description

Try fitting all models that differ from the current model by adding or deleting a single term from those supplied while maintaining marginality.

### Usage

addterm.clm2 5

### **Arguments**

object	A clm2 object.		
scope	for addterm: a formula specifying a maximal model which should include t current one. All additional terms in the maximal model with all marginal term in the original model are tried. For dropterm: a formula giving terms whi might be dropped. By default, the model formula. Only terms that can dropped and maintain marginality are actually tried.		
scale	used in the definition of the AIC statistic for selecting the models. Specifying scale asserts that the dispersion is known.		
test	should the results include a test statistic relative to the original model? The Chisq test is a likelihood-ratio test.		
k	the multiple of the number of degrees of freedom used for the penalty. Only $k=2$ gives the genuine AIC: $k = log(n)$ is sometimes referred to as BIC or SBC.		
sorted	should the results be sorted on the value of AIC?		
trace	if TRUE additional information may be given on the fits as they are tried.		
which	should additions or deletions occur in location or scale models?		
	arguments passed to or from other methods.		

# **Details**

The definition of AIC is only up to an additive constant because the likelihood function is only defined up to an additive constant.

### Value

A table of class "anova" containing columns for the change in degrees of freedom, AIC and the likelihood ratio statistic. If test = "Chisq" a column also contains the p-value from the Chisq test.

# **Examples**

6 anova.clm2

anova.clm2

Likelihood ratio test of cumulative link models

### **Description**

Comparison of cumulative link models in likelihood ratio tests. The models may differ by terms in location, scale and nominal formulae, in link, threshold function and random effect structure.

# Usage

```
## S3 method for class 'clm2'
anova(object, ..., test = c("Chisq", "none"))
## S3 method for class 'clmm2'
anova(object, ..., test = c("Chisq", "none"))
```

# **Arguments**

object a clm2 object.

... one or more additional clm2 objects.

test if test = "none" the p-value for the likelihood ratio test is suppressed.

#### Value

The method returns an object of class Anova (for printing) and data.frame with the following elements

Model character description of the cumulative link models being compared. Location,

scale and nominal formulae are separated by "I"s in this order.

Resid.df the residual degrees of freedom

-2logLik twice the negative log likelihood (proportional to the deviance)

Test indication of which models are being compared.

DF the difference in the degrees of freedom in the models being compared, i.e. the degrees of freedom for the chi-squared test.

LR stat. the likelihood ratio statistic.

Pr(Chi) the p-value from the likelihood ratio test. Absent if test = "none".

```

### **Examples**

clm

Cumulative Link Models

# Description

Fits cumulative link models (CLMs) such as the propotional odds model. The model allows for various link functions and structured thresholds that restricts the thresholds or cut-points to be e.g., equidistant or symmetrically arranged around the central threshold(s). Nominal effects (partial proportional odds with the logit link) are also allowed. A modified Newton algorithm is used to optimize the likelihood function.

# Usage

```
clm(formula, scale, nominal, data, weights, start, subset, doFit = TRUE,
  na.action, contrasts, model = TRUE, control=list(),
  link = c("logit", "probit", "cloglog", "loglog", "cauchit"),
  threshold = c("flexible", "symmetric", "symmetric2", "equidistant"), ...)
```

#### **Arguments**

formula a formula expression as for regression models, of the form response ~ predictors.

The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and will be ignored. An offset may be used. See the documentation of formula for other

details.

scale an optional formula expression, of the form ~ predictors, i.e. with an empty

left hand side. An offset may be used. Variables included here will have multiplicative effects and can be interpreted as effects on the scale (or dispersion) of

a latent distribution.

nominal an optional formula of the form ~ predictors, i.e. with an empty left hand

side. The effects of the predictors in this formula are assumed to be nominal rather than ordinal - this corresponds to the so-called partial proportional odds

(with the logit link).

data an optional data frame in which to interpret the variables occurring in the for-

mulas.

weights optional case weights in fitting. Defaults to 1. Negative weights are not allowed.

start initial values for the parameters in the format c(alpha, beta, zeta), where

alpha are the threshold parameters (adjusted for potential nominal effects),

beta are the regression parameters and zeta are the scale parameters.

subset expression saying which subset of the rows of the data should be used in the fit.

All observations are included by default.

doFit logical for whether the model should be fit or the model environment should be

returned.

na.action a function to filter missing data. Applies to terms in all three formulae.

contrasts a list of contrasts to be used for some or all of the factors appearing as variables

in the model formula.

model logical for whether the model frame should be part of the returned object.

control a list of control parameters passed on to clm. control.

link link function, i.e., the type of location-scale distribution assumed for the latent

distribution. The default "logit" link gives the proportional odds model.

threshold specifies a potential structure for the thresholds (cut-points). "flexible" pro-

vides the standard unstructured thresholds, "symmetric" restricts the distance between the thresholds to be symmetric around the central one or two thresholds for odd or equal numbers or thresholds respectively, "symmetric2" restricts the latent mean in the reference group to zero; this means that the central threshold (even no. response levels) is zero or that the two central thresholds are equal apart from their sign (uneven no. response levels), and "equidistant" restricts

the distance between consecutive thresholds to be of the same size.

... additional arguments are passed on to clm.control.

#### **Details**

This is a new (as of August 2011) improved implementation of CLMs. The old implementation is available in clm2, but will probably be removed at some point.

There are methods for the standard model-fitting functions, including summary, anova, model.frame, model.matrix, drop1, dropterm, step, stepAIC, extractAIC, AIC, coef, nobs, profile, confint, vcov and slice.

#### Value

If doFit = FALSE the result is an environment representing the model ready to be optimized. If doFit = TRUE the result is an object of class "clm" with the components listed below.

Note that some components are only present if scale and nominal are used.

aliased list of length 3 or less with components alpha, beta and zeta each being logical

vectors containing alias information for the parameters of the same names.

alpha a vector of threshold parameters.

alpha.mat (where relevant) a table (data.frame) of threshold parameters where each row

corresponds to an effect in the nominal formula.

beta (where relevant) a vector of regression parameters.

call the mathed call.

coefficients a vector of coefficients of the form c(alpha, beta, zeta)

cond.H Condition number of the Hessian matrix at the optimum (i.e. the ratio of the

largest to the smallest eigenvalue).

contrasts (where relevant) the contrasts used for the formula part of the model.

control List of control parameters as generated by clm.control.

convergence convergence code where 0 indicates successful convergence; 1 indicates the it-

eration limit was reached before convergence; 2 indicates the step factor was reduced below minimum before convergence was reached; 3 indicates that thresh-

olds are not increasing (only possible with nominal effects).

edf the estimated degrees of freedom, i.e., the number of parameters in the model

fit.

fitted.values the fitted probabilities.

gradient a vector of gradients for the coefficients at the estimated optimum.

Hessian the Hessian matrix for the parameters at the estimated optimum.

info a table of basic model information for printing.

link character, the link function used.

logLik the value of the log-likelihood at the estimated optimum.

maxGradient the maximum absolute gradient, i.e., max(abs(gradient)).

model if requested (the default), the model.frame containing variables from formula,

scale and nominal parts.

n the number of observations counted as nrow(X), where X is the design matrix.

na.action	(where relevant) information returned by model.frame on the special handling of NAs.
nobs	the number of observations counted as sum(weights).
nom.contrasts	(where relevant) the contrasts used for the nominal part of the model.
nom.terms	(where relevant) the terms object for the nominal part.
nom.xlevels	(where relevant) a record of the levels of the factors used in fitting for the nominal part.
start	the parameter values at which the optimization has started. An attribute start.iter gives the number of iterations to obtain starting values for models where scale is specified or where the cauchit link is chosen.
S.contrasts	(where relevant) the contrasts used for the scale part of the model.
S.terms	(where relevant) the terms object for the scale part.
S.xlevels	(where relevant) a record of the levels of the factors used in fitting for the scale part.
terms	the terms object for the formula part.
Theta	(where relevant) a table (data.frame) of thresholds for all combinations of levels of factors in the nominal formula.
threshold	character, the threshold structure used.
tJac	the transpose of the Jacobian for the threshold structure.
xlevels	(where relevant) a record of the levels of the factors used in fitting for the formula part.
y.levels	the levels of the response variable after removing levels for which all weights are zero.
zeta	(where relevant) a vector of scale regression parameters.

clm.control

Set control parameters for cumulative link models

# **Description**

Set control parameters for cumulative link models

# Usage

```
clm.control(method = c("Newton", "model.frame", "design", "ucminf", "nlminb",
    "optim"), ..., trace = 0L,
    maxIter = 100L, gradTol = 1e-06, maxLineIter = 15L, relTol = 1e-6,
    tol = sqrt(.Machine$double.eps), maxModIter = 5L,
    convergence = c("warn", "silent", "stop", "message"))
```

### **Arguments**

method	"Newton" fits the model by maximum likelihood and "model.frame" cause clm to return the model.frame, "design" causes clm to return a list of design matrices etc. that can be used with clm.fit.	
trace	numerical, if > 0 information is printed about and during the optimization process. Defaults to 0.	
maxIter	the maximum number of Newton-Raphson iterations. Defaults to 100.	
gradTol the maximum absolute gradient; defaults to 1e-6.		
maxLineIter	the maximum number of step halfings allowed if a Newton(-Raphson) step over shoots. Defaults to $10$ .	
relTol	relative convergence tolerence: relative change in the parameter estimates between Newton iterations. Defaults to 1e-6.	
tol	numerical tolerence on eigenvalues to determine negative-definiteness of Hessian. If the Hessian of a model fit is negative definite, the fitting algorithm did not converge. If the Hessian is singular, the fitting algorithm did converge albeit not to a <i>unique</i> optimum, so one or more parameters are not uniquely determined even though the log-likelihood value is.	
maxModIter	the maximum allowable number of consecutive iterations where the Newton step needs to be modified to be a decent direction. Defaults to 5.	
convergence	action to take if the fitting algorithm did not converge.	
	control arguments parsed on to ucminf, nlminb or optim.	

clm.fit

# Value

a list of control parameters.

# Author(s)

Rune Haubo B Christensen

# See Also

clm

clm.fit

Fit Cumulative Link Models

# **Description**

A direct fitter of cumulative link models.

# Usage

```
clm.fit(y, ...)
## Default S3 method:
clm.fit(y, ...)
## S3 method for class 'factor'
clm.fit(y, X, S, N, weights = rep(1, nrow(X)),
    offset = rep(0, nrow(X)), S.offset = rep(0, nrow(X)),
    control = list(), start, doFit=TRUE,
    link = c("logit", "probit", "cloglog", "loglog", "cauchit"),
    threshold = c("flexible", "symmetric", "symmetric2", "equidistant"),
    ...)
```

### **Arguments**

У	for the default method a list of model components. For the factor method the response variable; a factor, preferably and ordered factor.	
X, S, N	optional design matrices for the regression parameters, scale parameters and nominal parameters respectively.	
weights	optional case weights.	
offset	an optional offset.	
S.offset	an optional offset for the scale part of the model.	
control	a list of control parameters, optionally a call to clm.control.	

14 clm.fit

an optional list of starting values of the form c(alpha, beta, zeta) for the thresholds and nominal effects (alpha), regression parameters (beta) and scale parameters (zeta).

doFit logical for whether the model should be fit or the model environment should be

returned.

link the link function.

threshold the threshold structure, see further at clm.

... currently not used.

#### **Details**

This function does almost the same thing that clm does: it fits a cumulative link model. The main differences are that clm.fit does not setup design matrices from formulae and only does minimal post processing after parameter estimation.

Compared to clm, clm.fit does little to warn the user of any problems with data or model. However, clm.fit will attempt to identify column rank defecient designs. Any unidentified parameters are indicated in the aliased component of the fit.

clm.fit.factor is not able to check if all thresholds are increasing when nominal effects are specified since it needs access to the terms object for the nominal model. If the terms object for the nominal model (nom. terms) is included in y, the default method is able to chech if all thresholds are increasing.

### Value

A list with the following components: aliased, alpha, coefficients, cond.H, convergence, df.residual, and optionally beta, zeta These components are documented in clm.

edf.

```
mf1$control$method <- "Newton"
res2 <- clm.fit(mf1)
stopifnot(all.equal(coef(res2), coef(fm1)))</pre>
```

clm2

Cumulative link models

### **Description**

A new improved implementation of CLMs is available in clm.

Fits cumulative link models with an additive model for the location and a multiplicative model for the scale. The function allows for structured thresholds. A popular special case of a CLM is the proportional odds model. In addition to the standard link functions, two flexible link functions, "Arandar-Ordaz" and "log-gamma" are available, where an extra link function parameter provides additional flexibility. A subset of the predictors can be allowed to have nominal rather than ordinal effects. This has been termed "partial proportional odds" when the link is the logistic.

# Usage

```
clm2(location, scale, nominal, data, weights, start, subset,
   na.action, contrasts, Hess = TRUE, model,
   link = c("logistic", "probit", "cloglog", "loglog",
   "cauchit", "Aranda-Ordaz", "log-gamma"), lambda,
   doFit = TRUE, control,
   threshold = c("flexible", "symmetric", "equidistant"), ...)
```

### **Arguments**

location	a formula expression as for regression models, of the form response ~ predictors. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and will be ignored. An offset may be used. See the documentation of formula for other details.
scale	a optional formula expression as for the location part, of the form ~ predictors, i.e. with an empty left hand side. An offset may be used. See the documentation of formula for other details.
nominal	an optional formula of the form ~ predictors, i.e. with an empty left hand side. The effects of the predictors in this formula are assumed to nominal.
data	an optional data frame in which to interpret the variables occurring in the formulas.
weights	optional case weights in fitting. Defaults to 1.
start	initial values for the parameters in the format $c(alpha, beta, log(zeta), lambda)$ .
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

na.action a function to filter missing data. Applies to terms in all three formulae.

contrasts a list of contrasts to be used for some or all of the factors appearing as variables

in the model formula.

Hess logical for whether the Hessian (the inverse of the observed information matrix)

should be computed. Use Hess = TRUE if you intend to call summary or vcov on the fit and Hess = FALSE in all other instances to save computing time. The argument is ignored if method = "Newton" where the Hessian is always

computed and returned. Defaults to TRUE.

model logical for whether the model frames should be part of the returned object.

link link function, i.e. the type of location-scale distribution assumed for the latent

distribution. The Aranda-Ordaz and log-gamma links add additional flexibility with a link function parameter, lambda. The Aranda-Ordaz link (Aranda-Ordaz, 1983) equals the logistic link, when lambda = 1 and approaches the loglog link when lambda approaches zero. The log-gamma link (Genter and Farewell, 1985) equals the loglog link when lambda = 1, the probit link

when lambda = 0 and the cloglog link when lambda = -1.

lambda numerical scalar: the link function parameter. Used in combination with link

Aranda-Ordaz or log-gamma and otherwise ignored. If lambda is specified, the model is estimated with lambda fixed at this value and otherwise lambda is estimated by ML. For Aranda-Ordaz lambda has to be positive; > 1e-5 for

numerical reasons.

doFit logical for whether the model should be fit or the model environment should be

returned.

control a call to clm2.control.

threshold specifies a potential structure for the thresholds (cut-points). "flexible" pro-

vides the standard unstructured thresholds, "symmetric" restricts the distance between the thresholds to be symmetric around the central one or two thresholds for odd or equal numbers or thresholds respectively, and "equidistant"

restricts the distance between consecutive thresholds to the same value.

.. additional arguments are passed on to clm2.control and possibly further on

to the optimizer, which can lead to surprising error or warning messages when

mistyping arguments etc.

#### **Details**

There are methods for the standard model-fitting functions, including summary, vcov, predict, anova, logLik, profile, plot.profile, confint, update, dropterm, addterm, and an extractAIC method.

The design of the implementation is inspired by an idea proposed by Douglas Bates in the talk "Exploiting sparsity in model matrices" presented at the DSC conference in Copenhagen, July 14 2009. Basically an environment is set up with all the information needed to optimize the likelihood function. Extractor functions are then used to get the value of likelihood at current or given parameter values and to extract current values of the parameters. All computations are performed inside the environment and relevant variables are updated during the fitting process. After optimizer termination relevant variables are extracted from the environment and the remaining are discarded.

clm2 17

Some aspects of clm2, for instance, how starting values are obtained, and of the associated methods are inspired by polr from package MASS.

#### Value

If doFit = FALSE the result is an environment representing the model ready to be optimized. If doFit = TRUE the result is an object of class "clm2" with the following components:

beta the parameter estimates of the location part.

zeta the parameter estimates of the scale part on the log scale; the scale parameter

estimates on the original scale are given by exp(zeta).

Alpha vector or matrix of the threshold parameters.

Theta vector or matrix of the thresholds.

xi vector of threshold parameters, which, given a threshold function (e.g. "equidistant"),

and possible nominal effects define the class boundaries, Theta.

lambda the value of lambda if lambda is supplied or estimated, otherwise missing.

coefficients the coefficients of the intercepts (theta), the location (beta), the scale (zeta),

and the link function parameter (lambda).

df.residual the number of residual degrees of freedoms, calculated using the weights.

fitted.values vector of fitted values for each observation. An observation here is each of the

scalar elements of the multinomial table and not a multinomial vector.

convergence TRUE if the gradient based convergence criterion is met and FALSE otherwise. gradient vector of gradients for all the parameters at termination of the optimizer.

optRes list with results from the optimizer. The contents of the list depends on the

choice of optimizer.

logLik the log likelihood of the model at optimizer termination.

Hessian if the model was fitted with Hess = TRUE, this is the Hessian matrix of the

parameters at the optimum.

scale model.frame for the scale model.
location model.frame for the location model.
nominal model.frame for the nominal model.

edf the (effective) number of degrees of freedom used by the model.

start the starting values.

convTol convergence tolerance for the maximum absolute gradient of the parameters at

termination of the optimizer.

method character, the optimizer.
y the response variable.

lev the names of the levels of the response variable.

nobs the (effective) number of observations, calculated as the sum of the weights.

threshold character, the threshold function used in the model.

estimLambda 1 if lambda is estimated in one of the flexible link functions and 0 otherwise.

link character, the link function used in the model.

call the matched call.

contrasts applied to terms in location and scale models.

na.action the function used to filter missing data.

anova(m1, mT1, mT2)
## Extend example from polr in package MASS:
## Fit model from polr example:
if(require(MASS)) {
    fm1 <- clm2(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)</pre>
    fm1
    summary(fm1)
    ## With probit link:
    summary(update(fm1, link = "probit"))
    ## Allow scale to depend on Cont-variable
    summary(fm2 <- update(fm1, scale =~ Cont))</pre>
    anova(fm1, fm2)
    ## which seems to improve the fit
}
## It is possible to fit multinomial models (i.e. with nominal
## effects) as the following example shows:
if(require(nnet)) {
    (hous1.mu <- multinom(Sat ~ 1, weights = Freq, data = housing))</pre>
    (hous1.clm <- clm2(Sat ~ 1, weights = Freq, data = housing))</pre>
    ## It is the same likelihood:
    all.equal(logLik(hous1.mu), logLik(hous1.clm))
    ## and the same fitted values:
    fitHous.mu <-
        t(fitted(hous1.mu))[t(col(fitted(hous1.mu)) == unclass(housing$Sat))]
    all.equal(fitted(hous1.clm), fitHous.mu)
    ## The coefficients of multinom can be retrieved from the clm2-object
    Pi <- diff(c(0, plogis(hous1.clm$xi), 1))
    log(Pi[2:3]/Pi[1])
    ## A larger model with explanatory variables:
    (hous.mu <- multinom(Sat ~ Infl + Type + Cont, weights = Freq, data = housing))</pre>
```

20 clm2.control

clm2.control

Set control parameters for cumulative link models

# Description

Set control parameters for cumulative link models

# Usage

# **Arguments**

method	the optimizer used to maximize the likelihood function. "Newton" only works for models without scale, structured thresholds and flexible link functions, but is considerably faster than the other optimizers when applicable. model.frame simply returns a list of model frames with the location, scale and nominal model frames. "optim" uses the "BFGS" method.
	control arguments passed on to the chosen optimizer; see $ucminf$ , $optim$ , and $nlminb$ for details.
convTol	convergence criterion on the size of the maximum absolute gradient.
trace	numerical, if > 0 information is printed about and during the optimization process. Defaults to $\emptyset$ .
maxIter	the maximum number of Newton-Raphson iterations. Defaults to 100.
gradTol	the maximum absolute gradient. This is the termination criterion and defaults to $1e-5$ .
maxLineIter	the maximum number of step halfings allowed if a Newton(-Raphson) step over shoots. Defaults to $10$ .

clmm 21

# Value

a list of control parameters.

### Author(s)

Rune Haubo B Christensen

# See Also

clm2

 ${\tt clmm}$ 

Cumulative Link Mixed Models

# **Description**

Fits Cumulative Link Mixed Models with one or more random effects via the Laplace approximation or quadrature methods

# Usage

```
clmm(formula, data, weights, start, subset, na.action, contrasts, Hess =
TRUE, model = TRUE, link = c("logit", "probit", "cloglog", "loglog",
"cauchit"), doFit = TRUE, control = list(), nAGQ = 1L,
threshold = c("flexible", "symmetric", "symmetric2", "equidistant"), ...)
```

### **Arguments**

formula	a two-sided linear formula object describing the fixed-effects part of the mode with the response on the left of a ~ operator and the terms, separated by + operators, on the right. The vertical bar character "I" separates an expression for model matrix and a grouping factor.	
data	an optional data frame in which to interpret the variables occurring in the formula.	
weights	optional case weights in fitting. Defaults to 1.	
start	optional initial values for the parameters in the format c(alpha, beta, tau), where alpha are the threshold parameters, beta are the fixed regression parameters and tau are variance parameters for the random effects on the log scale.	
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.	
na.action	a function to filter missing data.	
contrasts	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.	

22 clmm

Hess logical for whether the Hessian (the inverse of the observed information matrix)

should be computed. Use Hess = TRUE if you intend to call summary or vcov on the fit and Hess = FALSE in all other instances to save computing time.

logical for whether the model frames should be part of the returned object.

link link function, i.e. the type of location-scale distribution assumed for the latent

distribution. The default "logit" link gives the proportional odds mixed model.

doFit logical for whether the model should be fit or the model environment should be

returned.

control a call to clmm. control

nAGQ integer; the number of quadrature points to use in the adaptive Gauss-Hermite

quadrature approximation to the likelihood function. The default (1) gives the Laplace approximation. Higher values generally provide higher precision at the expense of longer computation times, and values between 5 and 10 generally provide accurate maximum likelihood estimates. Negative values give the non-adaptive Gauss-Hermite quadrature approximation, which is generally faster but less accurate than the adaptive version. See the references for further details. Quadrature methods are only available with a single random effects term; the

Laplace approximation is always available.

threshold specifies a potential structure for the thresholds (cut-points). "flexible" pro-

vides the standard unstructured thresholds, "symmetric" restricts the distance between the thresholds to be symmetric around the central one or two thresholds for odd or equal numbers or thresholds respectively, and "equidistant"

restricts the distance between consecutive thresholds to the same value.

... additional arguments are passed on to clm.control.

### **Details**

mode1

This is a new (as of August 2011) improved implementation of CLMMs. The old implementation is available in clmm2. Some features are not yet available in clmm; for instance scale effects, nominal effects and flexible link functions are currently only available in clmm2. clmm is expected to take over clmm2 at some point.

There are standard print, summary and anova methods implemented for "clmm" objects.

### Value

a list containing

alpha threshold parameters.

beta fixed effect regression parameters.

stDev standard deviation of the random effect terms.

tau log(stDev) - the scale at which the log-likelihood function is optimized.

coefficients the estimated model parameters = c(alpha, beta, tau).

control List of control parameters as generated by clm. control.

Hessian Hessian of the model coefficients.

edf the estimated degrees of freedom used by the model = length(coefficients).

clmm.control 23

nobs sum(weights).
n length(y).

fitted.values fitted values evaluated with the random effects at their conditional modes.

df.residual residual degrees of freedom; length(y) - sum(weights)

tJac Jacobian of the threshold function corresponding to the mapping from standard

flexible thresholds to those used in the model.

terms the terms object for the fixed effects.

contrasts contrasts applied to the fixed model terms.

na.action the function used to filter missing data.

call the matched call.

logLik value of the log-likelihood function for the model at the optimum.

Niter number of Newton iterations in the inner loop update of the conditional modes

of the random effects.

optRes list of results from the optimizer.

ranef list of the conditional modes of the random effects.

condVar list of the conditional variance of the random effects at their conditional modes.

#### Author(s)

Rune Haubo B Christensen

# **Examples**

clmm.control

Set control parameters for cumulative link mixed models

### **Description**

Set control parameters for cumulative link mixed models

24 clmm2

### Usage

```
clmm.control(method = c("nlminb", "ucminf", "model.frame"), ..., trace = 0,
maxIter = 50, gradTol = 1e-4, maxLineIter = 50, useMatrix = FALSE,
innerCtrl = c("warnOnly", "noWarn", "giveError"))
```

### **Arguments**

method the optimizer used to maximize the marginal likelihood function.

... control arguments passed on to the optimizer; see ucminf for details. ucminf

for details.

trace numerical, if > 0 information is printed about and during the outer optimization

process, if < 0 information is also printed about the inner optimization process.

Defaults to 0.

maxIter the maximum number of Newton updates of the inner optimization. 50.

gradTol the maximum absolute gradient of the inner optimization.

maxLineIter the maximum number of step halfings allowed if a Newton(-Raphson) step over

shoots during the inner optimization.

useMatrix if TRUE, a general implementation of the Laplace approximation using the Matrix

package is used, while if FALSE (default), a C implementation of the Laplace approximation valid only for models with a single random effects term is used when possible. TRUE is not valid for models fitted with quadrature methods.

innerCtrl the use of warnings/errors if the inner optimization fails to converge.

#### Value

a list of control parameters

c1mm

clmm2	Cumulative link mixed models	

### Description

Fits cumulative link mixed models, i.e. cumulative link models with random effects via the Laplace approximation or the standard and the adaptive Gauss-Hermite quadrature approximation. The functionality in clm2 is also implemented here. Currently only a single random term is allowed in the location-part of the model.

A new implementation is available in clmm that allows for more than one random effect.

clmm2 25

### Usage

```
clmm2(location, scale, nominal, random, data, weights, start, subset,
    na.action, contrasts, Hess = FALSE, model = TRUE, sdFixed,
    link = c("logistic", "probit", "cloglog", "loglog",
    "cauchit", "Aranda-Ordaz", "log-gamma"), lambda,
    doFit = TRUE, control, nAGQ = 1,
    threshold = c("flexible", "symmetric", "equidistant"), ...)
```

### **Arguments**

mode1

random a factor for the random effects in the location-part of the model.

data as in clm2. weights as in clm2.

start initial values for the parameters in the format c(alpha, beta, log(zeta), lambda, log(stDev))

where stDev is the standard deviation of the random effects.

subset as in clm2.
na.action as in clm2.
contrasts as in clm2.

Hess logical for whether the Hessian (the inverse of the observed information matrix)

should be computed. Use Hess = TRUE if you intend to call summary or vcov on the fit and Hess = FALSE in all other instances to save computing time.

as in clm2.

sdFixed If sdFixed is specified (a positive scalar), a model is fitted where the standard

deviation for the random term is fixed at the value of sdFixed. If sdFixed is left unspecified, the standard deviation of the random term is estimated from data.

link as in clm2. lambda as in clm2.

doFit as in clm2 although it can also be one of c("no", "R" "C"), where "R" use

the R-implementation for fitting, "C" (default) use C-implementation for fitting

and "no" behaves as FALSE and returns the environment.

control a call to clmm2.control.

threshold as in clm2.

nAGQ the number of quadrature points to be used in the adaptive Gauss-Hermite quadra-

ture approximation to the marginal likelihood. Defaults to 1 which leads to the Laplace approximation. An odd number of quadrature points is encouraged and 3, 5 or 7 are usually enough to achive high precision. Negative values give the

standard, i.e. non-adaptive Gauss-Hermite quadrature.

... additional arguments are passed on to clm2.control and possibly further on

to the optimizer, which can lead to surprising error or warning messages when

mistyping arguments etc.

26 clmm2

#### **Details**

There are methods for the standard model-fitting functions, including summary, vcov, profile, plot.profile, confint, anova, logLik, predict and an extractAIC method.

A Newton scheme is used to obtain the conditional modes of the random effects for Laplace and AGQ approximations, and a non-linear optimization is performed over the fixed parameter set to get the maximum likelihood estimates. The Newton scheme uses the observed Hessian rather than the expected as is done in e.g. glmer, so results from the Laplace approximation for binomial fits should in general be more precise - particularly for other links than the "logistic".

Core parts of the function are implemented in C-code for speed.

The function calls clm2 to up an environment and to get starting values.

#### Value

condVar

If doFit = FALSE the result is an environment representing the model ready to be optimized. If doFit = TRUE the result is an object of class "clmm2" with the following components:

stDev the standard deviation of the random effects.

Ni ter the total number of iterations in the Newton updates of the conditional modes of the random effects.

grFac the grouping factor defining the random effects.

nAGQ the number of quadrature points used in the adaptive Gauss-Hermite Quadrature approximation to the marginal likelihood.

ranef the conditional modes of the random effects, sometimes referred to as "random effect estimates".

the conditional variances of the random effects at their conditional modes.

beta the parameter estimates of the location part.

zeta the parameter estimates of the scale part on the log scale; the scale parameter

estimates on the original scale are given by exp(zeta).

Alpha vector or matrix of the threshold parameters.

Theta vector or matrix of the thresholds.

xi vector of threshold parameters, which, given a threshold function (e.g. "equidistant"),

and possible nominal effects define the class boundaries, Theta.

lambda the value of lambda if lambda is supplied or estimated, otherwise missing.

coefficients the coefficients of the intercepts (theta), the location (beta), the scale (zeta),

and the link function parameter (lambda).

df.residual the number of residual degrees of freedoms, calculated using the weights.

fitted.values vector of fitted values conditional on the values of the random effects. Use

predict to get the fitted values for a random effect of zero. An observation here is taken to be each of the scalar elements of the multinomial table and not

a multinomial vector.

convergence TRUE if the optimizer terminates without error and FALSE otherwise.

gradient vector of gradients for the unit-variance random effects at their conditional modes.

clmm2 27

optRes list with results from the optimizer. The contents of the list depends on the

choice of optimizer.

logLik the log likelihood of the model at optimizer termination.

Hessian if the model was fitted with Hess = TRUE, this is the Hessian matrix of the

parameters at the optimum.

scale model.frame for the scale model.

location model.frame for the location model.

nominal model.frame for the nominal model.

edf the (effective) number of degrees of freedom used by the model.

start the starting values.

method character, the optimizer.

y the response variable.

lev the names of the levels of the response variable.

nobs the (effective) number of observations, calculated as the sum of the weights.

threshold character, the threshold function used in the model.

estimLambda 1 if lambda is estimated in one of the flexible link functions and 0 otherwise.

link character, the link function used in the model.

call the matched call.

contrasts contrasts applied to terms in location and scale models.

na.action the function used to filter missing data.

clmm2

Confidence intervals and profile likelihoods for parameters in cumu-
lative link models

# Description

Computes confidence intervals from the profiled likelihood for one or more parameters in a cumulative link model, or plots the profile likelihood.

# Usage

30 confint

```
profile(fitted, which.beta = seq_len(nbeta),
             which.zeta = seq_len(nzeta), alpha = 0.001,
             max.steps = 50, nsteps = 8, trace = FALSE, step.warn = 5,
             control = list(), ...)
    ## S3 method for class 'profile.clm'
    plot(x, which.par = seq_len(nprofiles),
             level = c(0.95, 0.99), Log = FALSE, relative = TRUE, root =
             FALSE, fig = TRUE, approx = root, n = 1e3,
             ask = prod(par("mfcol")) < length(which.par) && dev.interactive(),</pre>
              ..., ylim = NULL)
Arguments
    object, fitted, x
                      a fitted clm object or a profile.clm object.
    parm, which.par, which.beta, which.zeta
                      a numeric or character vector indicating which regression coefficients should
                      be profiled. By default all coefficients are profiled. Ignored for confint.clm
                      where all parameters are considered.
    level
                      the confidence level. For the plot method a vector of levels for which horizontal
                      lines should be drawn.
                      the type of confidence interval.
    type
                      if trace is TRUE or positive, information about progress is printed.
    trace
                      should the profile likelihood be plotted on the log-scale?
    Log
                      should the relative or the absolute likelihood be plotted?
    relative
    root
                      should the (approximately linear) likelihood root statistic be plotted?
                      should the Gaussian or quadratic approximation to the (log) likelihood be in-
    approx
                      cluded?
                      should the profile likelihood be plotted?
    fig
    ask
                      logical; if TRUE, the user is asked before each plot, see par(ask=.).
                      the no. points used in the spline interpolation of the profile likelihood.
    ylim
                      overrules default y-limits on the plot of the profile likelihood.
    alpha
                      The likelihood is profiled in the 100*(1-alpha)% confidence region as deter-
                      mined by the profile likelihood.
    control
                      a list of control parameters for clm. Possibly use clm. control to set these.
                      the maximum number of profiling steps in each direction for each parameter.
    max.steps
                      the (approximate) number of steps to take in each direction of the profile for
    nsteps
                      each parameter. The step length is determined accordingly assuming a quadratic
                      approximation to the log-likelihood function. The actual number of steps will
                      often be close to nsteps, but will deviate when the log-likelihood functions is
                      a warning is issued if the number of steps in each direction (up or down) for
    step.warn
                      a parameter is less than step. warn. If few steps are taken, the profile will be
                      unreliable and derived confidence intervals will be inaccurate.
                      additional arguments to be parsed on to methods.
```

confint 31

#### **Details**

These confint methods call the appropriate profile method, then finds the confidence intervals by interpolation of the profile traces. If the profile object is already available, this should be used as the main argument rather than the fitted model object itself.

#### Value

confint: A matrix with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

plot.profile.clm invisibly returns the profile object, i.e., a list of data.frames with an lroot component for the likelihood root statistic and a matrix par.vals with values of the parameters.

confint.clm2

Confidence intervals and profile likelihoods for parameters in cumulative link models

# Description

Computes confidence intervals from the profiled likelihood for one or more parameters in a fitted cumulative link model, or plots the profile likelihood function.

### Usage

# **Arguments**

object a fitted clm2 object or a profile.clm2 object.

fitted a fitted clm2 object.

x a profile.clm2 object.

parm not used in confint.clm2.

For confint.profile.clm2: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.

For plot.profile.clm2: a specification of which parameters the profile likelihood are to be plotted for, either a vector of numbers or a vector of names. If missing, all parameters are considered. confint.clm2 33

level the confidence level required. a specification of which location parameters are to be given confidence interwhichL vals, either a vector of numbers or a vector of names. If missing, all location parameters are considered. whichS a specification of which scale parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all scale parameters are considered. lambda logical. Should profile or confidence intervals be computed for the link function parameter? Only used when one of the flexible link functions are used; see the link-argument in clm2. logical. Should profiling be traced? trace alpha Determines the range of profiling. By default the likelihood is profiled in the 99% confidence interval region as determined by the profile likelihood. the maximum number of profiling steps in each direction (up and down) for each maxSteps parameter. delta the length of profiling steps. To some extent this parameter determines the degree of accuracy of the profile likelihood in that smaller values, i.e. smaller steps gives a higher accuracy. Note however that a spline interpolation is used when constructing confidence intervals so fairly long steps can provide high accuracy. stepWarn a warning is issued if the no. steps in each direction (up or down) for a parameter is less than stepWarn (defaults to 8 steps) because this indicates an unreliable profile. should the profile likelihood be plotted on the log-scale? Log relative should the relative or the absolute likelihood be plotted? should the profile likelihood be plotted? fig the no. points used in the spline interpolation of the profile likelihood. overrules default y-limits on the plot of the profile likelihood. ylim

#### **Details**

These confint methods call the appropriate profile method, then finds the confidence intervals by interpolation of the profile traces. If the profile object is already available, this should be used as the main argument rather than the fitted model object itself.

additional argument(s) for methods including range (for the hidden function profileLambda) that sets the range of values of lambda at which the likelihood

In plot.profile.clm2: at least one of Log and relative arguments have to be TRUE.

should be profiled for this parameter.

#### Value

confint: A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%). The parameter names are preceded with "loc." or "sca." to indicate whether the confidence interval applies to a location or a scale parameter.

plot.profile.clm2 invisibly returns the profile object.

convergence 35

CO	nve	roe	nce

Check convergence of cumulative link models

#### **Description**

Check the accuracy of the parameter estimates of cumulative link models. The number of correct decimals and number of significant digits is given for the maximum likelihood estimates of the parameters in a cumulative link model fitted with clm.

### Usage

```
convergence(object, ...)
## S3 method for class 'clm'
convergence(object, digits = max(3, getOption("digits") - 3),
   tol = sqrt(.Machine$double.eps), ...)
```

#### **Arguments**

object	for the clm method an object of class "clm", i.e., the result of a call to clm.
digits	the number of digits in the printed table.
tol	numerical tolerence to judge if the Hessian is positive definite from its smallest eigenvalue.
	arguments to a from methods. Not used by the clm method.

### **Details**

The number of correct decimals is defined as...

The number of significant digits is defined as ...

The number of correct decimals and the number of significant digits are determined from the numerical errors in the parameter estimates. The numerical errors are determined from the Method Independent Error Theorem (Elden et al, 2004) and is based on the Newton step evaluated at convergence.

### Value

Convergence information. In particular a table where the Error column gives the numerical error in the parameter estimates. These numbers express how far the parameter estimates in the fitted model are from the true maximum likelihood estimates for this model. The Cor.Dec gives the number of correct decimals with which the parameters are determined and the Sig.Dig gives the number of significant digits with which the parameters are determined.

The number denoted logLik.error is the error in the value of log-likelihood in the fitted model at the parameter values of that fit. An accurate determination of the log-likelihood is essential for accurate likelihood ratio tests in model comparison.

drop.coef

Ensure Full Rank Design Matrix

# **Description**

Coefficients (columns) are dropped from a design matrix to ensure that it has full rank.

### Usage

```
drop.coef(X, silent = FALSE)
```

# **Arguments**

Χ

a design matrix, e.g., the result of model.matrix possibly of less than full column rank, i.e., with redundant parameters. Works for  $ncol(X) \ge 0$  and

nrow(X) >= 0.

silent

should a message not be issued if X is column rank deficient?

# **Details**

Redundant columns of the design matrix are identified with the LINPACK implementation of the qr decomposition and removed. The returned design matrix will have qr(X)\$rank columns.

# Value

The design matrix X without redundant columns.

# Author(s)

Rune Haubo B Christensen

ncol(newX)

## Essentially this is being computed:
qr.X <- qr(X, tol = 1e-7, LAPACK = FALSE)
newX <- X[, qr.X$pivot[1:qr.X$rank], drop = FALSE]
## is newX of full column rank?
ncol(newX) == qr(newX)$rank
## the number of columns being dropped:
ncol(X) - ncol(newX)</pre>
```

gfun

Gradients of common densities

# **Description**

Gradients of common density functions in their standard forms, i.e., with zero location (mean) and unit scale. These are implemented in C for speed and care is taken that the correct results are provided for the argument being NA, NaN, Inf, -Inf or just extremely small or large.

# Usage

```
gnorm(x)
glogis(x)
gcauchy(x)
```

## **Arguments**

Х

numeric vector of quantiles.

#### **Details**

The gradients are given by:

38 gumbel

• gnorm: If f(x) is the normal density with mean 0 and spread 1, then the gradient is

$$f'(x) = -xf(x)$$

• glogis: If f(x) is the logistic density with mean 0 and scale 1, then the gradient is

$$f'(x) = 2\exp(-x)^2(1 + \exp(-x))^{-3} - \exp(-x)(1 + \exp(-x))^{-2}$$

• peauchy: If  $f(x) = [\pi(1+x^2)^2]^{-1}$  is the cauchy density with mean 0 and scale 1, then the gradient is

$$f'(x) = -2x[\pi(1+x^2)^2]^{-1}$$

These gradients are used in the Newton-Raphson algorithms in fitting cumulative link models with clm and cumulative link mixed models with clmm.

#### Value

a numeric vector of gradients.

## Author(s)

Rune Haubo B Christensen

#### See Also

Gradients of densities are also implemented for the extreme value distribtion (gumbel) and the the log-gamma distribution (log-gamma).

# **Examples**

```
x <- -5:5
gnorm(x)
glogis(x)
gcauchy(x)</pre>
```

gumbel

The Gumbel Distribution

# **Description**

Density, distribution function, quantile function, random generation, and gradient of density of the extreme value (maximum and minimum) distributions. The Gumbel distribution is also known as the extreme value maximum distribution, the double-exponential distribution and the log-Weibull distribution.

gumbel 39

#### Usage

```
dgumbel(x, location = 0, scale = 1, log = FALSE, max = TRUE)
pgumbel(q, location = 0, scale = 1, lower.tail = TRUE, max = TRUE)
qgumbel(p, location = 0, scale = 1, lower.tail = TRUE, max = TRUE)
rgumbel(n, location = 0, scale = 1, max = TRUE)
ggumbel(x, max = TRUE)
```

# **Arguments**

x,q numeric vector of quantiles.p vector of probabilities.n number of observations.

location numeric scalar. scale numeric scalar.

lower.tail logical; if TRUE (default), probabilities are  $P[X \le x]$  otherwise, P[X > x].

logical; if TRUE, probabilities p are given as log(p).

max distribution for extreme maxima (default) or minima? The default corresponds

to the standard right-skew Gumbel distribution.

#### **Details**

dgumbel, pgumbel and ggumbel are implemented in C for speed and care is taken that 'correct' results are provided for values of NA, NaN, Inf, -Inf or just extremely small or large.

See the 'Primer' vignette for the definition of the Gumbel distribution and its relation to the log-log and complementary-log-log link used in cumulative link models. See the examples for numerical relations between the max and min variants.

The distribution functions, densities and gradients are used in the Newton-Raphson algorithms in fitting cumulative link models with clm and cumulative link mixed models with clmm.

#### Value

pgumbel gives the distribution function, dgumbel gives the density, ggumbel gives the gradient of the density, ggumbel is the quantile function, and rgumbel generates random deviates.

```

42 Igamma

lgamma

The log-gamma distribution

#### **Description**

Density, distribution function and gradient of density for the log-gamma distribution. These are implemented in C for speed and care is taken that the correct results are provided for values of NA, NaN, Inf, -Inf or just extremely small or large values.

The log-gamma is a flexible location-scale distribution on the real line with an extra parameter,  $\lambda$ . For  $\lambda=0$  the distribution equals the normal or Gaussian distribution, and for  $\lambda$  equal to 1 and -1, the Gumbel minimum and maximum distributions are obtained.

# Usage

```
plgamma(q, lambda, lower.tail = TRUE)
dlgamma(x, lambda, log = FALSE)
glgamma(x, lambda)
```

# **Arguments**

x,q numeric vector of quantiles.

lambda numerical scalar

lower.tail logical; if TRUE (default), probabilities are  $P[X \le x]$  otherwise, P[X > x].

logical; if TRUE, probabilities p are given as log(p).

#### **Details**

If  $\lambda < 0$  the distribution is right skew, if  $\lambda = 0$  the distribution is symmetric (and equals the normal distribution), and if  $\lambda > 0$  the distribution is left skew.

The log-gamma distribution function is defined as ... pending.

The density and gradient of the density are defined as...pending.

These distribution functions, densities and gradients are used in the Newton-Raphson algorithms in fitting cumulative link models with clm2 and cumulative link mixed models with clmm2 using the log-gamma link.

#### Value

plgamma gives the distribution function, dlgamma gives the density and glgamma gives the gradient of the density.

nominal\_test 43

Gradients of densities are also implemented for the normal, logistic, cauchy, cf. gfun and the Gumbel distribution, cf. gumbel.

```
## Illustrating the link to other distribution functions:
x < -5:5
plgamma(x, lambda = 0) == pnorm(x)
all.equal(plgamma(x, lambda = -1), pgumbel(x)) ## TRUE, but:
plgamma(x, lambda = -1) == pgumbel(x)
plgamma(x, lambda = 1) == pgumbel(x, max = FALSE)
dlgamma(x, lambda = 0) == dnorm(x)
dlgamma(x, lambda = -1) == dgumbel(x)
dlgamma(x, lambda = 1) == dgumbel(x, max = FALSE)
glgamma(x, lambda = 0) == gnorm(x)
all.equal(glgamma(x, lambda = -1), ggumbel(x)) ## TRUE, but:
glgamma(x, lambda = -1) == ggumbel(x)
all.equal(glgamma(x, lambda = 1), ggumbel(x, max = FALSE)) ## TRUE, but:
glgamma(x, lambda = 1) == ggumbel(x, max = FALSE)
## There is a loss of accuracy, but the difference is very small:
glgamma(x, lambda = 1) - ggumbel(x, max = FALSE)
## More examples:
x <- -5:5
plgamma(x, lambda = .5)
dlgamma(x, lambda = .5)
glgamma(x, lambda = .5)
```

44 nominal\_test

## **Description**

Add all model terms to scale and nominal formulae and perform likelihood ratio tests. These tests can be viewed as goodness-of-fit tests. With the logit link, nominal\_test provides likelihood ratio tests of the proportional odds assumption. The scale\_test tests can be given a similar interpretation

#### Usage

```
nominal_test(object, ...)
## S3 method for class 'clm'
nominal_test(object, scope, trace=FALSE, ...)
scale_test(object, ...)
## S3 method for class 'clm'
scale_test(object, scope, trace=FALSE, ...)
```

# **Arguments**

object	for the clm method an object of class "clm", i.e., the result of a call to clm.
scope	a formula or character vector specifying the terms to add to scale or nominal. In nominal_test terms in scope already in nominal are ignored. In scale_test terms in scope already in scale are ignored.
	In nominal_test the default is to add all terms from formula (location part) and scale that are not also in nominal.
	In scale_test the default is to add all terms from formula (location part) that are not also in scale.
trace	if TRUE additional information may be given on the fits as they are tried.
	arguments passed to or from other methods.

#### **Details**

The definition of AIC is only up to an additive constant because the likelihood function is only defined up to an additive constant.

## Value

A table of class "anova" containing columns for the change in degrees of freedom, AIC, the likelihood ratio statistic and a p-value based on the asymptotic chi-square distribtion of the likelihood ratio statistic under the null hypothesis.

## Author(s)

Rune Haubo B Christensen

   nominal_test(fm1)
   ## Evidence of multiplicative/scale effect of 'Cont'. This is a breach
   ## of the proportional odds assumption.
}
```

predict.clm

Predict Method for CLM fits

# **Description**

Obtains predictions from a cumulative link model.

# Usage

## **Arguments**

object

a fitted object of class inheriting from clm.

newdata

optionally, a data frame in which to look for variables with which to predict. Note that all predictor variables should be present having the same names as the variables used to fit the model. If the response variable is present in newdata predictions are obtained for the levels of the response as given by newdata. If the response variable is omitted from newdata predictions are obtained for all levels of the response variable for each of the rows of newdata.

46 predict.clm

se.fit should standard errors of the predictions be provided? Not applicable and ig-

nored when type = "class".

interval should confidence intervals for the predictions be provided? Not applicable and

ignored when type = "class".

level the confidence level.

type the type of predictions. "prob" gives probabilities, "class" gives predicted re-

sponse class membership defined as highest probability prediction, "cum.prob" gives cumulative probabilities (see details) and "linear.predictor" gives predictions on the scale of the linear predictor including the boundary categories.

na.action function determining what should be done with missing values in newdata. The

default is to predict NA.

... further arguments passed to or from other methods.

#### **Details**

If newdata is omitted and type = "prob" a vector of fitted probabilities are returned identical to the result from fitted.

If newdata is supplied and the response variable is omitted, then predictions, standard errors and intervals are matrices rather than vectors with the same number of rows as newdata and with one column for each response class. If type = "class" predictions are always a vector.

If newdata is omitted, the way missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with residual value NA. See also napredict.

If type = "cum.prob" or type = "linear.predictor" there will be two sets of predictions, standard errors and intervals; one for j and one for j-1 (in the usual notation) where j = 1, ..., J index the response classes.

If newdata is supplied and the response variable is omitted, then predict.clm returns much the same thing as predict.polr (matrices of predictions). Similarly, if type = "class".

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued (cf. predict.lm).

#### Value

A list containing the following components

fit predictions or fitted values if newdata is not supplied.

se.fit if se.fit=TRUE standard errors of the predictions otherwise NULL.

upr, lwr if interval=TRUE lower and upper confidence limits.

## **Examples**

predict.clm2

Predict Method for CLM fits

# Description

Obtains predictions from a cumulative link (mixed) model.

#### Usage

```
## S3 method for class 'clm2'
predict(object, newdata, ...)
```

# Arguments

object a fitted object of class inheriting from clm2 including clmm2 objects.

newdata optionally, a data frame in which to look for variables with which to predict.

Observe that the response variable should also be present.

... further arguments passed to or from other methods.

48 predict.clm2

#### **Details**

This method does not duplicate the behavior of predict.polr in package MASS which produces a matrix instead of a vector of predictions. The behavior of predict.polr can be mimiced as shown in the examples.

If newdata is not supplied, the fitted values are obtained. For clmm2 fits this means predictions that are controlled for the observed value of the random effects. If the predictions for a random effect of zero, i.e. an average 'subject', are wanted, the same data used to fit the model should be supplied in the newdata argument. For clm2 fits those two sets of predictions are identical.

#### Value

A vector of predicted probabilities.

    all.equal(class.clm, class.polr) ## TRUE
}
```

profile.clmm2

Confidence intervals and profile likelihoods for the standard deviation for the random term in cumulative link mixed models

## **Description**

Computes confidence intervals from the profiled likelihood for the standard devation for the random term in a fitted cumulative link mixed model, or plots the associated profile likelihood function.

# Usage

# Arguments

```
object a fitted profile.clmm2 object.

fitted a fitted clmm2 object.

x a profile.clmm2 object.
```

50 profile.clmm2

parm	For confint.profile.clmm2: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered. Currently only "stDev" or 1 are supported.
	For plot.profile.clmm2: a specification of which parameters the profile likelihood are to be plotted for, either a vector of numbers or a vector of names. If missing, all parameters are considered. Currently only "stDev" or 1 are supported.
level	the confidence level required. Observe that the model has to be profiled in the appropriate region; otherwise the limits are NA.
trace	logical. Should profiling be traced? Defaults to TRUE due to the time consuming nature of the computation.
alpha	Determines the range of profiling. By default the likelihood is profiled approximately in the 99% confidence interval region as determined by the Wald approximation. This is usually sufficient for 95% profile likelihood confidence limits.
range	if range is specified, this overrules the range computation based on alpha. range should be all positive and stDev is profiled in range(range).
nSteps	the number of points at which to profile the likelihood function. This determines the resolution and accuracy of the profile likelihood function; higher values gives a higher resolution, but also longer computation times.
Log	should the profile likelihood be plotted on the log-scale?
relative	should the relative or the absolute likelihood be plotted?
fig	should the profile likelihood be plotted?
n	the no. points used in the spline interpolation of the profile likelihood for plotting.
ylim	overrules default y-limits on the plot of the profile likelihood.
• • •	additional argument(s), e.g. graphical parameters for the plot method.

# **Details**

A confint.clmm2 method deliberately does not exist due to the time consuming nature of the computations. The user is required to compute the profile object first and then call confint on the profile object to obtain profile likelihood confidence intervals.

In plot.profile.clm2: at least one of Log and relative arguments have to be TRUE.

# Value

confint: A matrix with columns giving lower and upper confidence limits. These will be labelled as (1-level)/2 and 1-(1-level)/2 in % (by default 2.5% and 97.5%).

plot.profile.clm2 invisibly returns the profile object.

        incidence <- as.factor(rep(0:1, each=nrow(cbpp)))</pre>
        freq <- with(cbpp, c(incidence, size - incidence))</pre>
    })
    ## Fit with Laplace approximation:
    fm1 <- clmm2(incidence ~ period, random = herd, weights = freq,</pre>
                  data = cbpp2, Hess = 1)
    pr.fm1 <- profile(fm1)</pre>
    confint(pr.fm1)
    par(mfrow = c(2,2))
    plot(pr.fm1)
    plot(pr.fm1, Log=TRUE, relative = TRUE)
    plot(pr.fm1, Log=TRUE, relative = FALSE)
}
```

ranef

Extract conditional modes and conditional variances from clmm objects

#### **Description**

The ranef function extracts the conditional modes of the random effects from a clmm object. That is, the modes of the distributions for the random effects given the observed data and estimated model parameters. In a Bayesian language they are posterior modes.

The conditional variances are computed from the second order derivatives of the conditional distribution of the random effects. Note that these variances are computed at a fixed value of the model parameters and thus do not take the uncertainty of the latter into account.

# Usage

```
ranef(object, ...)
condVar(object, ...)
## S3 method for class 'clmm'
```

52 ranef

```
ranef(object, condVar=FALSE, ...)
## S3 method for class 'clmm'
condVar(object, ...)
```

# **Arguments**

object a clmm object.

condVar an optional logical argument indicating of conditional variances should be added

as attributes to the conditional modes.

... currently not used by the clmm methods.

#### **Details**

The ranef method returns a list of data.frames; one for each distinct grouping factor. Each data.frame has as many rows as there are levels for that grouping factor and as many columns as there are random effects for each level. For example a model can contain a random intercept (one column) or a random intercept and a random slope (two columns) for the same grouping factor.

If conditional variances are requested, they are returned in the same structure as the conditional modes (random effect estimates/predictions).

#### Value

The ranef method returns a list of data.frames with the random effects predictions/estimates computed as conditional modes. If condVar = TRUE a data.frame with the conditional variances is stored as an attribute on each data.frame with conditional modes.

The condVar method returns a list of data. frames with the conditional variances. It is a convenience function that simply computes the conditional modes and variances, then extracts and returns only the latter.

## Author(s)

Rune Haubo B Christensen

```
fm1 <- clmm(rating ~ contact + temp + (1|judge), data=wine)
## Extract random effect estimates/conditional modes:
re <- ranef(fm1, condVar=TRUE)
## Get conditional variances:
attr(re$judge, "condVar")
## Alternatively:
condVar(fm1)</pre>
```

slice 53

slice	Slice the likelihood of a clm

# **Description**

Slice likelihood and plot the slice. This is usefull for illustrating the likelihood surface around the MLE (maximum likelihood estimate) and provides graphics to substantiate (non-)convergence of a model fit. Also, the closeness of a quadratic approximation to the log-likelihood function can be inspected for relevant parameters. A slice is considerably less computationally demanding than a profile.

# Usage

```
slice(object, ...)
## S3 method for class 'clm'
slice(object, parm = seq_along(par), lambda = 3,
    grid = 100, quad.approx = TRUE, ...)
## S3 method for class 'slice.clm'
plot(x, parm = seq_along(x),
    type = c("quadratic", "linear"), plot.mle = TRUE,
    ask = prod(par("mfcol")) < length(parm) && dev.interactive(), ...)</pre>
```

# Arguments

object	for the clm method an object of class "clm", i.e., the result of a call to clm.
x	a slice.clm object, i.e., the result of slice(clm.object).
parm	for slice.clm a numeric or character vector indexing parameters, for plot.slice.clm only a numeric vector is accepted. By default all parameters are selected.
lambda	the number of curvature units on each side of the MLE the slice should cover.
grid	the number of values at which to compute the log-likelihood for each parameter.
quad.approx	compute and include the quadratic approximation to the log-likelihood function?
type	"quadratic" plots the log-likelihood function which is approximately quadratic, and "linear" plots the signed square root of the log-likelihood function which is approximately linear.
plot.mle	include a vertical line at the MLE (maximum likelihood estimate) when type = "quadratic"? Ignored for type = "linear".
ask	logical; if TRUE, the user is asked before each plot, see par(ask=.).
• • •	further arguments to plot.default for the plot method. Not used in the slice method.

54 soup

#### Value

The slice method returns a list of data.frames with one data.frame for each parameter slice. Each data.frame contains in the first column the values of the parameter and in the second column the values of the (positive) log-likelihood "logLik". A third column is present if quad.approx = TRUE and contains the corresponding quadratic approximation to the log-likelihood. The original model fit is included as the attribute "original.fit".

The plot method produces a plot of the likelihood slice for each parameter.

# Author(s)

Rune Haubo B Christensen

# **Examples**

```
## fit model:
fm1 <- clm(rating ~ contact + temp, data = wine)
## slice the likelihood:
sl1 <- slice(fm1)

## three different ways to plot the slices:
par(mfrow = c(2,3))
plot(sl1)
plot(sl1, type = "quadratic", plot.mle = FALSE)
plot(sl1, type = "linear")

## Verify convergence to the optimum:
sl2 <- slice(fm1, lambda = 1e-5, quad.approx = FALSE)
plot(sl2)</pre>
```

soup

Discrimination study of packet soup

## **Description**

The soup data frame has 1847 rows and 13 variables. 185 respondents participated in an A-not A discrimination test with sureness. Before experimentation the respondents were familiarized with the reference product and during experimentation, the respondents were asked to rate samples on an ordered scale with six categories given by combinations of (reference, not reference) and (sure, not sure, guess) from 'reference, sure' = 1 to 'not reference, sure' = 6.

## Usage

soup

update.clm2 55

#### **Format**

RESP factor with 185 levels: the respondents in the study.

PROD factor with 2 levels: index reference and test products.

PRODID factor with 6 levels: index reference and the five test product variants.

SURENESS ordered factor with 6 levels: the respondents ratings of soup samples.

DAY factor with two levels: experimentation was split over two days.

SOUPTYPE factor with three levels: the type of soup regularly consumed by the respondent.

SOUPFREQ factor with 3 levels: the frequency with which the respondent consumes soup.

COLD factor with two levels: does the respondent have a cold?

EASY factor with ten levels: How easy did the respondent find the discrimation test? 1 = difficult, 10 = easy.

GENDER factor with two levels: gender of the respondent.

AGEGROUP factor with four levels: the age of the respondent.

LOCATION factor with three levels: three different locations where experimentation took place.

#### Source

Data are produced by Unilever Research. Permission to publish the data is granted.

update.clm2

Update method for cumulative link models

## **Description**

```
Update method for cumulative link models fitted with clm2. This makes it possible to use e.g. update(obj, location = \sim . - var1, scale = \sim . + var2)
```

# Usage

56 VarCorr

# **Arguments**

object	a clm2 object.
formula.	not used—unfortunately this argument is part of the default method.
location	an optional new formula for the location; see update.formula for details.
scale	an optional new formula for the scale; see update.formula for details.
nominal	an optional new formula for nominal effects; see update.formula for details.
	additional arguments to the call, or arguments with changed values.
evaluate	if true evaluate the new call else return the call.

#### Value

If evaluate = TRUE the fitted object is returned, otherwise the updated call.

# Author(s)

Rune Haubo B Christensen

# **Examples**

VarCorr

Extract variance and correlation parameters

# **Description**

The VarCorr function extracts the variance and (if present) correlation parameters for random effect terms in a cumulative link mixed model (CLMM) fitted with clmm.

# Usage

```
VarCorr(x, ...)
## S3 method for class 'clmm'
VarCorr(x, ...)
```

wine 57

## Arguments

x a clmm object.

... currently not used by the clmm method.

#### **Details**

The VarCorr method returns a list of data.frames; one for each distinct grouping factor. Each data.frame has as many rows as there are levels for that grouping factor and as many columns as there are random effects for each level. For example a model can contain a random intercept (one column) or a random intercept and a random slope (two columns) for the same grouping factor.

If conditional variances are requested, they are returned in the same structure as the conditional modes (random effect estimates/predictions).

#### Value

A list of matrices with variances in the diagonal and correlation parameters in the off-diagonal — one matrix for each random effects term in the model. Standard deviations are provided as attributes to the matrices.

#### Author(s)

Rune Haubo B Christensen

# **Examples**

```
fm1 <- clmm(rating ~ contact + temp + (1|judge), data=wine)
VarCorr(fm1)</pre>
```

wine

Bitterness of wine

# Description

The wine data set is adopted from Randall(1989) and from a factorial experiment on factors determining the bitterness of wine. Two treatment factors (temperature and contact) each have two levels. Temperature and contact between juice and skins can be controlled when cruching grapes during wine production. Nine judges each assessed wine from two bottles from each of the four treatment conditions, hence there are 72 observations in all.

# Usage

wine

58 wine

#### **Format**

```
response scorings of wine bitterness on a 0—100 continuous scale. rating ordered factor with 5 levels; a grouped version of response. temp temperature: factor with two levels. contact factor with two levels ("no" and "yes"). bottle factor with eight levels. judge factor with nine levels.
```

#### **Source**

Data are adopted from Randall (1989).
